# AIAA/IEEE Submission Binder Addendum

*CVP Artemis package expansion with canon and magnetospheric appendices*

v8 Addendum • Companion to Binder v7

**Scope.** This addendum is designed to sit after the existing binder v7. It adds the cross-domain CVP-B extension, a curated canon visual sequence, and an updated appendix map without disturbing the disciplined structure of the core manuscript.

## Manifest Additions

| Appendix | Item | Purpose |
|---|---|---|
| Appendix N | Canon Map | High-level architecture plate linking CVP-G, CVP-B, dispersion, syntropy, and package outputs. |
| Appendix O | Curated Canon Artifacts | Foundational visual plates retained as ceremonial/theorem-aligned support. |
| Appendix P | CVP-B Van Allen Extension | Cross-domain extension from lunar curvature to magnetospheric stability. |
| Appendix Q | Editorial Placement Note | Explains why the extension stays in the binder rather than the core paper. |

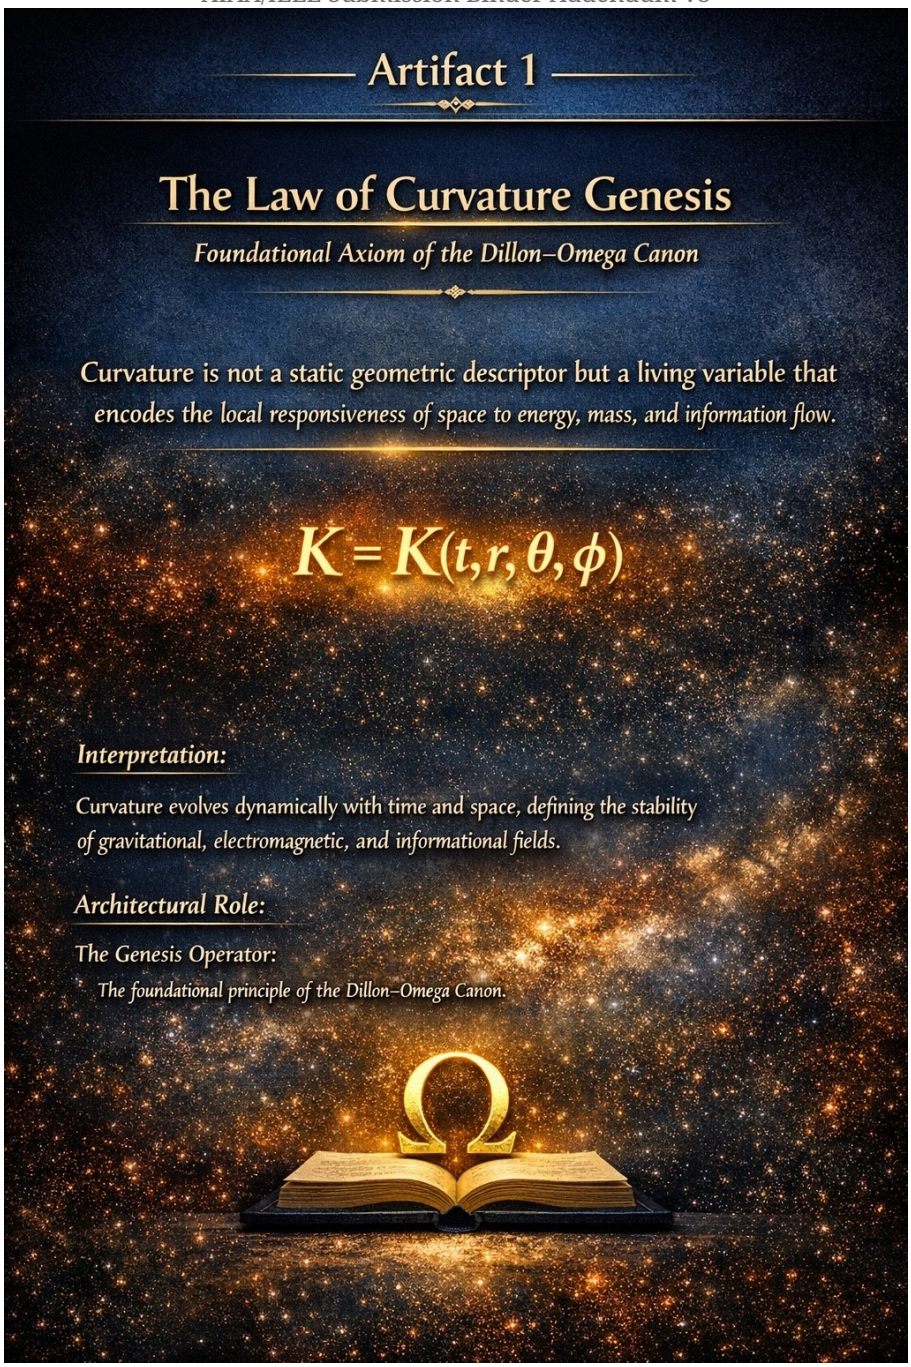
## Appendix N. Dillon-Omega Canon Map

The canon map is best used as an appendix opener: it translates the broader authored system into a single architecture plate without forcing that entire grammar into the AIAA/IEEE manuscript.

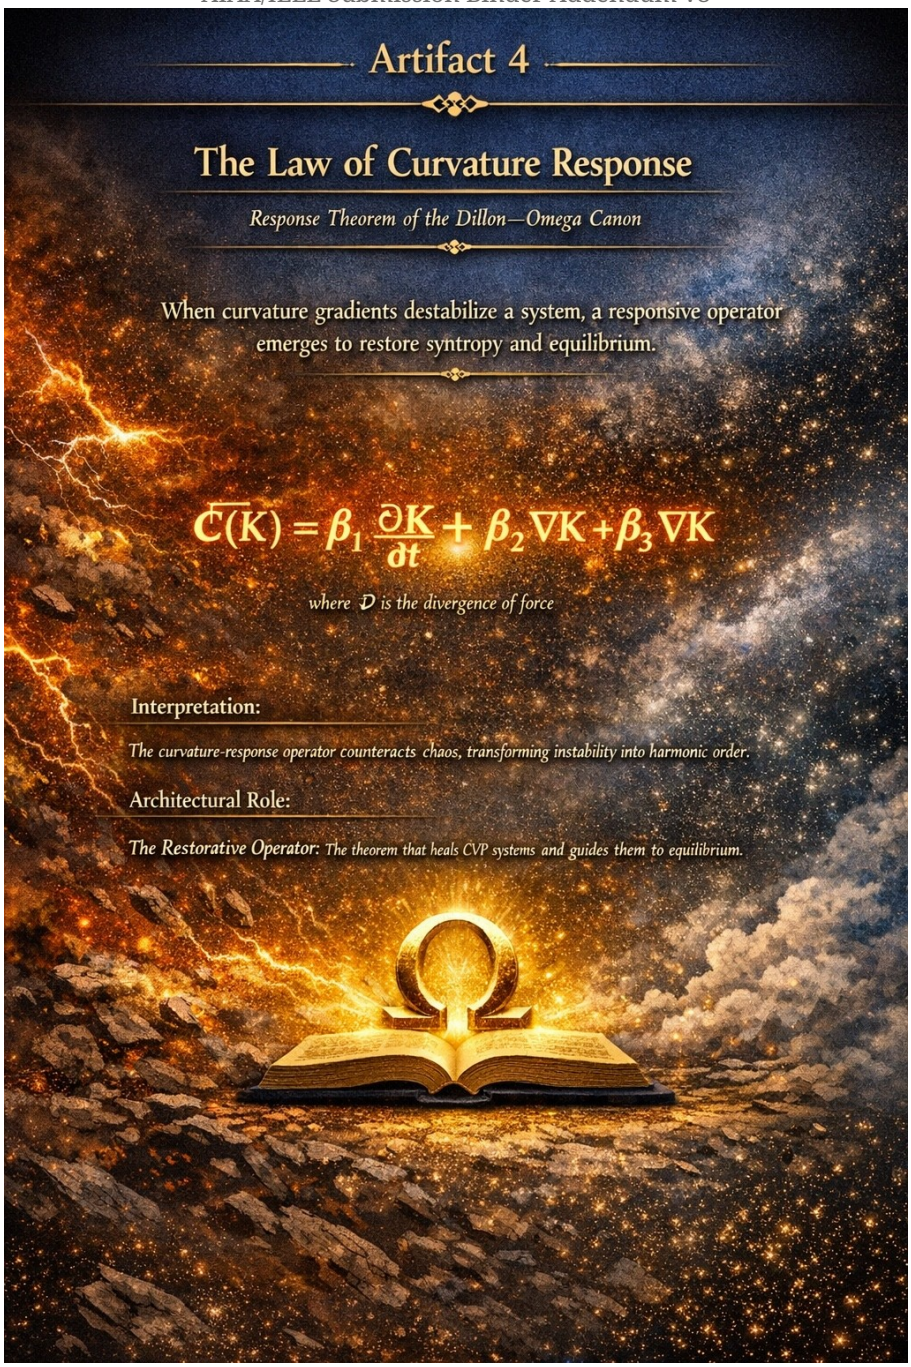
*Appendix Figure N-1. Dillon-Omega Canon Map.*

## Appendix O. Curated Canon Visuals

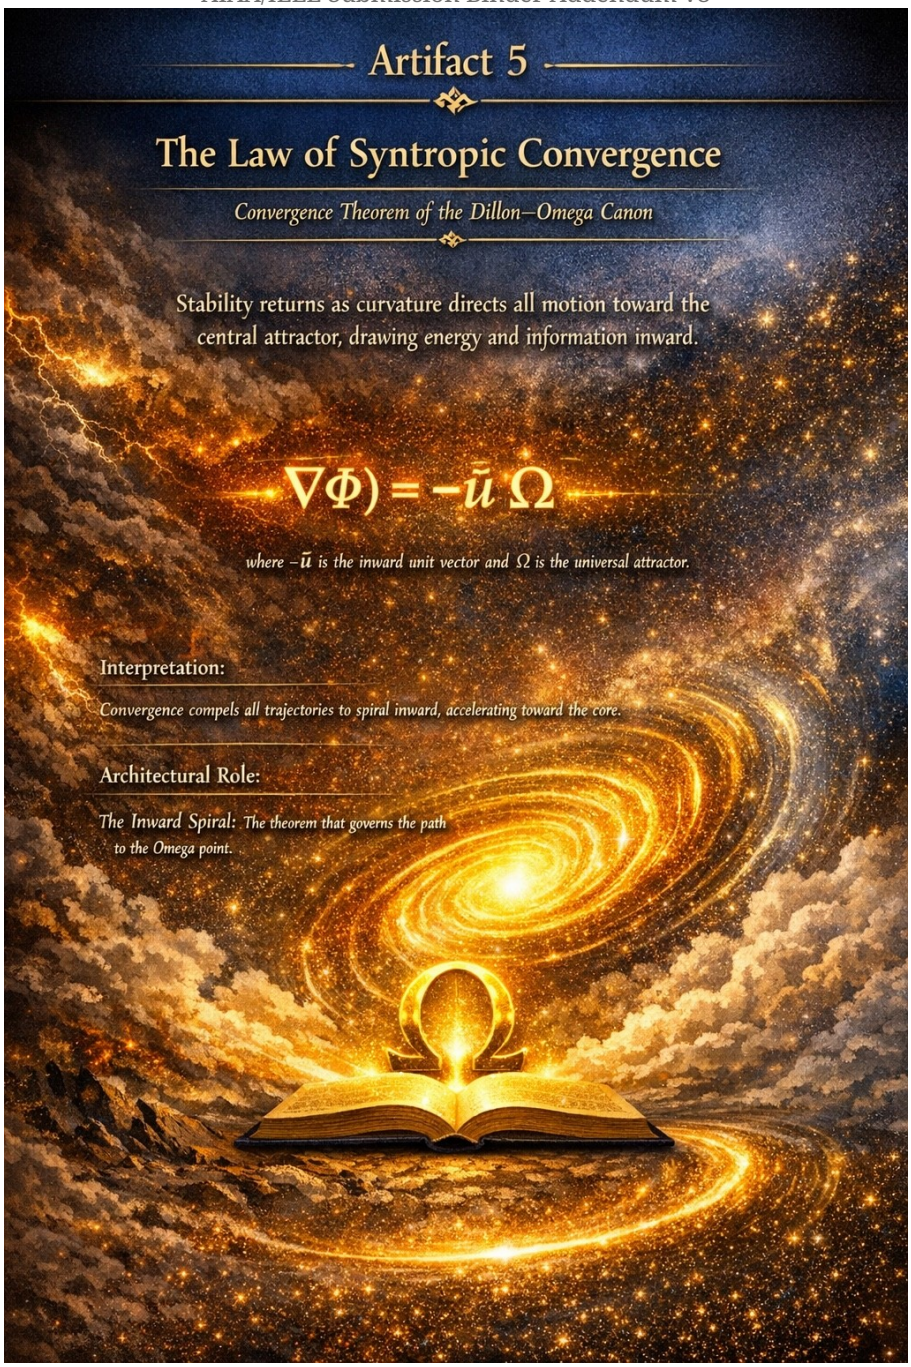
The technical binder should use a curated subset of the canon visuals rather than the full ceremonial run. The strongest plates for the current package are the foundational operator, the response operator, the syntropic convergence plate, and the universal attractor plate.



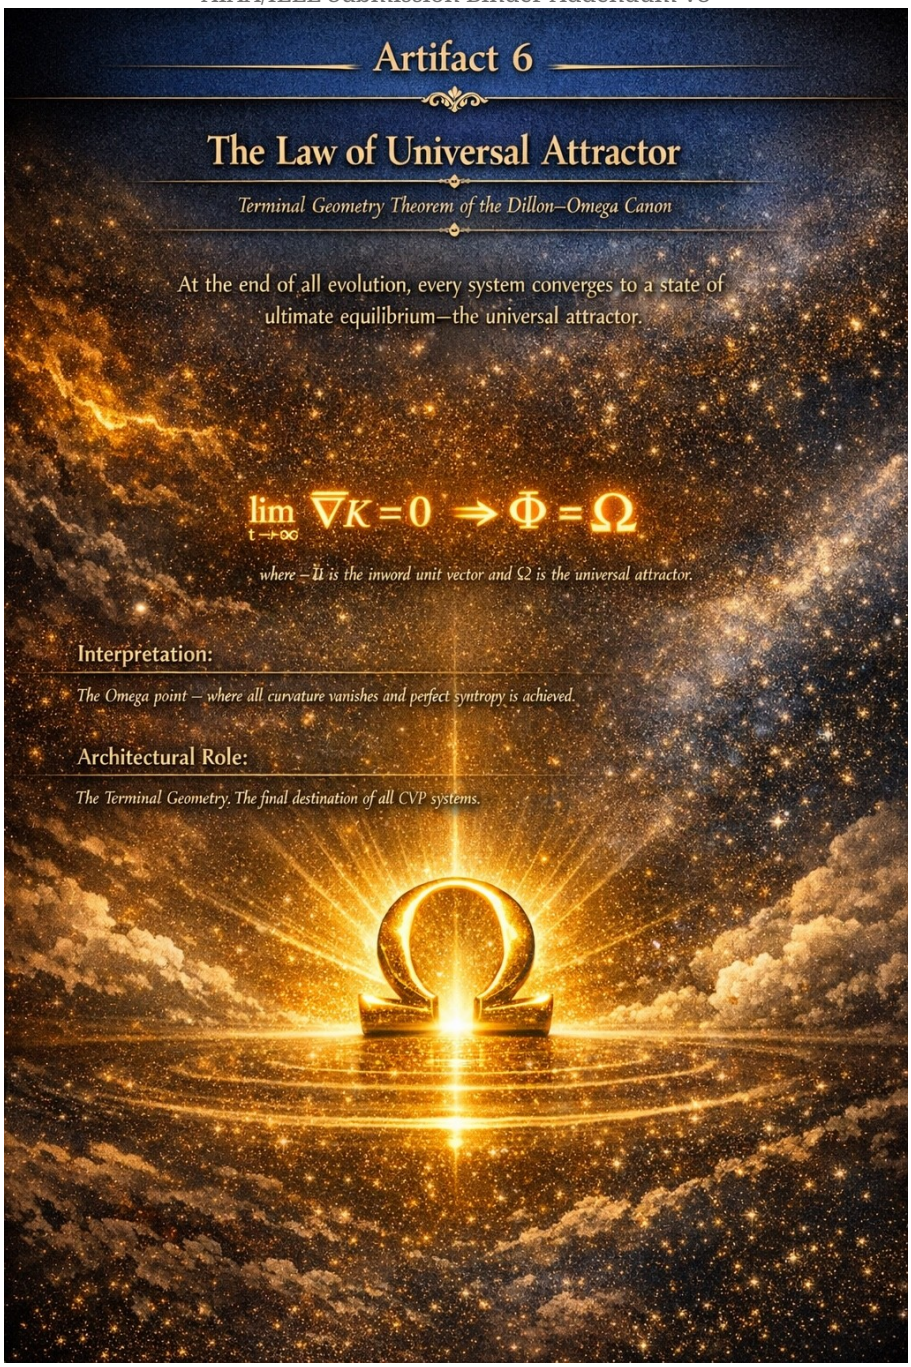
*Appendix Figure O-1. Artifact 1 - The Law of Curvature Genesis.*



*Appendix Figure O-2. Artifact 4 - The Law of Curvature Response.*



*Appendix Figure O-3. Artifact 5 - The Law of Syntropic Convergence.*



*Appendix Figure O-4. Artifact 6 - The Law of Universal Attractor.*

## Appendix P. Curvature Variable Physics Applied to the Van Allen Radiation Belts

The Van Allen extension is retained here as a formal supporting appendix, not as the core lunar proof. It generalizes the CVP grammar from gravitational curvature to magnetospheric curvature with coordinates K_B(t,L,α,φ), a magnetic divergence operator D_B, and a response operator C_B(K_B) selected to enforce a bounded, convergent electromagnetic manifold.

| Component | Binder framing |
|---|---|
| Dynamic field | K_B(t,L,α,φ) as a magnetospheric curvature field for |

| | |
|---|---|
| | trapped-particle stability. |
| Divergence | D_B as the electromagnetic analogue of the lunar dispersion spike during storm-time distortions. |
| Response operator | C_B(K_B) ports the CVP response grammar into the magnetospheric domain. |
| Convergence condition | Choose coefficients such that the corrected divergence is driven to zero. |
| Implementation | Reuse the GPU corridor simulator by replacing the lunar radial corridor with an L-shell corridor. |

**Placement note.**

The CVP-B extension is technically strong and visually coherent with the rest of the package, but it is still a second-domain application. Keeping it in the binder preserves the manuscript's discipline while opening a clear path for a later standalone magnetospheric paper or companion white paper.

## Appendix Q. Editorial Placement Note

**Why this split works.** The manuscript remains a focused Artemis proof document. The binder carries the broader research architecture, implementation path, strategic framing, and cross-domain canon.

**Recommended package lanes:**

- Journal manuscript: core lunar-descent proof, three technical figures, concise implementation note.
- Technical binder: manuscript, figure companion, code exhibit, DoD memo, canon map, and CVP-B extension.
- Canon supplement: curated visual sequence for archive, partner briefings, or ceremonial presentation.
