

CVP Spin Overlay

Integrity + reproducibility plane for distributed compute, cryptography, and governed control systems.

AI RELIABILITY

GPU INTEGRITY

TEVR PROOF

SELF-HEALING TRUST

Pitch objective

Advance the CVP Spin Overlay into NVIDIA-aligned design-partner pilots, technical diligence, and seed financing.

Timothy J. Dillon
Founder & Chief Inventor | 206 Innovation Inc.
Bellevue, Washington | 2026

One platform core; multiple governed trust lanes

Start with the highest-friction wedge, then expand the same architecture into regulated domains.

Core wedge

AI factories and distributed compute need boundary-first integrity: detect silent drift, localize first divergence, prevent stale-state propagation, and export replayable proof.

Product layer

CSO turns telemetry, kernel state, memory provenance, fabric events, and policy into governed runtime action and TEVR evidence packets.

Expansion engine

The same trust plane extends into cryptographic migration, telecom/network integrity, industrial/grid controls, and lunar/fusion governance.

1

reusable
core

Investment thesis: focused AI reliability entry point, expandable platform architecture, repeatable proof workflow.

Correctness breaks quietly at scale

The pain is not only throughput. It is proving what actually happened, where drift first appeared, and whether a run can be replayed.

Silent wrong

Plausible outputs can emerge from drifting or corrupted state without an obvious failure signal.

Non-determinism

Ranks, streams, reductions, atomics, and async overlap make failures hard to reproduce.

Rerun cost

GPU weeks can disappear into root-cause analysis instead of productive training or simulation.

Audit gap

Standard logs are not independently verifiable proof artifacts.

Customer pain: high-cost workloads increasingly require evidence, not just dashboards.

CVP Spin Overlay: an integrity-control plane above existing systems

Boundary instrumentation + policy control + replayable proof artifacts.

Position: not an observability dashboard; a control-and-proof layer for high-trust execution.

c remains local; c_eff governs effective propagation

The canonical notation prevents legacy variable-c language from weakening the technical story.

$$\mathbf{c_{eff}} = \mathbf{f(K, R, \nabla K, \partial_t K)}$$

Effective propagation is curvature-conditioned across structured geometry and state.

$$\mathbf{D(c_{eff}, h, \mathcal{G}) = (\delta c_{eff} / \delta \mathcal{G})|_h}$$

Formal Dillon Operator over metric/gravitational geometry at fixed informational scale h.

Local invariant

c is the local invariant causal speed; the deck does not claim local causality is modified.

Effective layer

c_eff models propagation, timing, coupling, and state transport across structured curvature and boundaries.

GPU analogy

c_eff^GPU maps tensor curvature, execution order, fabric gradients, and state-time evolution into one governance surface.

Canonical discipline makes the pitch compatible with serious technical diligence.

From telemetry to governed action

A reusable software stack designed for enterprise deployment and domain-pack expansion.

One reusable core engine; sector-specific semantics at the edges.

A raw compute trace becomes an admissible execution manifold

CSO evaluates tensor state, kernel metadata, scheduling, storage provenance, fabric telemetry, and hash linkage together.

$$I_{CSO}(t) = \{T_t, K_t, Q_t, M_t, F_t, H_t\}$$

State-integrity packet for distributed GPU and enterprise execution.

T_t

Tensor state + invariant signature

K_t

Kernel state + version

Q_t

Scheduling / queue state

M_t

Memory + storage provenance

F_t

Fabric telemetry

H_t

Hash-anchored metadata

$$S_{\{t+1\}} \in \Gamma_{\text{admissible}}(S_t, C(K_t), \Pi_t)$$

A state transition is accepted only when consistent with prior state, curvature response, and policy boundary.

Attach where customers already build

The implementation path is practical: kernels, collectives, storage, telemetry, validation, and service-plane policy.

CUDA wrappers

Kernel instrumentation, invariant checks, sampling policies, replay anchors.

NCCL boundary tags

Collective-boundary integrity and stale-state propagation detection.

GPUDirect Storage

End-to-end provenance from object/NVMe storage to GPU memory paths.

Fabric telemetry

NVLink, InfiniBand, Ethernet correlation for fault isolation.

Validator

Deterministic replay, policy tolerance, and proof-bundle verification.

Service plane

Policy DSL, approvals, rollback, incident artifacts, certification workflows.

Design principle: minimal workflow disruption, maximum evidence at the boundary.

Replayable proof becomes the product artifact

Transparent, Encrypted, Verifiable, and Reproducible evidence for engineering, diligence, compliance, and customer trust.

B_TEV = H(kernels, seeds, schedule, invariants, checkpoints, environment, policy)

Hash-anchored proof artifact for deterministic container replay and policy-tolerance review.

Engineering value

Find first divergence and reduce GPU-week reruns.

Governance value

Turn runtime behavior into reviewable evidence.

Commercial value

Certification, recertification, and workflow lock-in.

Near-term ship target: evidence packet standard + validator + replay pass/fail reports.

BCDE adds morphology-first structural audit

Binary strings, coefficients, tensor boundaries, execution traces, and session states are scored before trust or action.

BCDE is positioned as a defensive structural-audit layer for triage, governance, and controlled response.

Detection should trigger containment and restoration

The trust plane converts structural scoring into gated runtime actions.

$$\Theta_{op} = (H_{run}, \beta, E, \Gamma_{safe})$$

Operational trigger tuple for trust-state scoring and safe-path gating.

Policy-controlled action

A transition can be allowed, quarantined, rotated, rebound, isolated, replayed, or escalated based on admissibility and policy.

1

Gate isolation

Drop, quarantine, or freeze the active cryptographic or execution context.

2

Restructure

Shift parameters so the same deformity corridor cannot be reused.

3

Restore

Rotate affected state, update policy, issue signed alert, and preserve proof.

Trust is a runtime loop: detect, contain, recover, and preserve evidence.

Enterprise adoption path: inventory to continuous governance

This turns cryptographic transition into a practical buyer workflow.

Priority sectors

PKI, secure communications, code signing, archives, firmware trust, embedded systems, regulated AI, and distributed compute workloads.

NVIDIA-aligned pilot target

Start where GPU pipelines already face high cost from silent drift, replay failures, and audit requirements; then extend into cryptographic trust migration.

Migration message: score exposure, contain risk, replace primitives, govern continuously.

Lead with AI reliability and enterprise integrity

The wedge must be narrow enough for diligence and valuable enough for paid pilots.

Primary wedge

- Enterprise LLM training teams
- Distributed AI workloads
- Replayable proof for critical runs
- First-divergence localization
- Policy-gated exception routing
- Validator + evidence packet workflow

Expansion lanes

- Fraud and compliance
- Telecom and industrial monitoring
- Finance/wagering chain of custody
- Safety envelope + verified actuation
- Cryptographic migration governance
- Lunar/fusion control overlays

Focus creates immediate pilot value while preserving a broader platform moat.

Pilot to license to certification attach

The recurring moat is the evidence standard, validator, policy DSL, and recertification workflow.

Revenue streams

- Paid pilots
- Annual platform license
- Domain-pack subscriptions
- Validation workflows
- Verified certification
- Recertification renewal

Go-to-market

- Lighthouse pilots
- Engineering/value proof
- Convert to ARR
- Expand inside account
- Add regulated tier
- Attach certification

Moat

- Patent portfolio
- Policy DSL
- Schema + validator
- Evidence packet standard
- Certification workflow
- Switching cost

\$3.5M

Capital Connect seed application path

\$12M

Full-platform seed base case

2-3

design-partner pilots

Two raise configurations; one execution logic

A smaller Capital Connect path plus a larger platform seed base case.

Capital Connect configuration - \$3.5M

Objective: focused product readiness and first lighthouse pilot.

Use: engineering hardening, SDK readiness, validator prototype, evidence packet standard, one paid design partner, investor diligence package.

Best for: lower-friction seed application and partner validation.

Full-platform seed - \$12M

Objective: 12-18 months runway, 2-3 design partners, first production conversion.

Use: platform team, CUDA/NCCL/GDS implementation, certification profile, domain-pack roadmaps, enterprise GTM, cryptography and fusion validation tracks.

Best for: lead-driven institutional seed.

Lunar + fusion governance as a long-horizon control lane

The same integrity, invariants, recovery, and TEVR proof-bundle logic applies to high-consequence physical control.

Why He-3 matters

Aneutronic-oriented reactions can shift more energy into charged products, enabling direct electromagnetic conversion if confinement can be stabilized.

Control bottleneck

The gating risk is not only heating; it is turbulence-driven transport, edge drift, MHD instability, and bounded field geometry.

CVP role

Invariant-driven state, curvature-response actuation, strict local recovery, and TEVR proof bundles for repeatability.

Long-horizon positioning: governed control, reproducible evidence, and partner validation for high-consequence systems.

Make each layer falsifiable and replayable

Partner diligence should see staged gates, declared tolerances, and reproducible artifacts.

Software matrix

Boundary instrumentation, validator, proof bundles, first-divergence reports, replay tolerance, policy DSL.

GPU matrix

CUDA/NCCL/GDS workloads, multi-GPU runs, deterministic replay, fault injection, TEVR evidence.

Cryptography matrix

BCDE prototype, morphology metrics, exposure scoring, containment actions, audit logs, red-team review.

Fusion matrix

Phase A plasma testbed; Pi reduction, tau increase, recovery tests, replay bundles.

Validation standard: each claim advances through replay, tolerance checks, partner review, and documented evidence.

From partner deck to production conversion

A staged path for NVIDIA Inception, Capital Connect, and technical diligence.

Founder-led platform build with staged functional expansion

Move from integrated research and architecture into productized pilots, validator scope, and investor diligence.

Leadership

Timothy J. Dillon
Founder & Chief Inventor
206 Innovation Inc.
Bellevue, Washington

Core strengths: enterprise software architecture, deterministic state tracking, cross-sector IP positioning, platform commercialization strategy.

Partner next steps

1. Review technical whitepaper and partner deck.
2. Select 1-2 lighthouse pilot candidates.
3. Define validator and evidence-packet scope.
4. Align NVIDIA implementation path.
5. Confirm seed narrative and diligence package.

Ask: design-partner pilots, technical diligence, and seed-process alignment for the CSO platform.

Supplemental materials available for review

A structured package supports technical review, pilot planning, and investor diligence.

Core NVIDIA / CSO

Technical whitepaper
c_eff canonical update
CSO architecture brief
TEVR proof-bundle
specification

Supports: technical
diligence and
implementation review.

Cryptography / BCDE

Product materials
VC one-pager
Capital Connect deck
Pilot roadmap

Supports: investor
diligence and partner
conversations.

Lunar / Fusion / GNC

Expansion research
BCDE whitepaper
Cryptographic migration
notes
Lunar / fusion
governance papers

Supports: domain-pack
roadmap and future
validation.

Investor-facing claims are framed around product architecture, pilot validation, reproducible evidence, and defensible implementation milestones.
